2.5D Does Not Systematically Cut Organs Short; Where They Stop Varies More Between Patients Than Between Models

Change in where the predicted organ stops, per organ end, 2.5D − 2D per patient (40 patients, each averaged over 3 seeds). Big dot = mean, bar = 95% bootstrap interval, faint dots = individual patients.

Predicted ends = first and last slice of the longest unbroken run of slices with that organ predicted, on the original CT grid; error = distance from the ground-truth end slice, positive when the prediction stops short. Data: data/segthor_train_full/train, corrected labels. x-axis cut at ±20 mm.
