2.5D Changes Almost Nothing Mid-Organ; at Organ Ends the Effects Are Larger but Inconsistent

Paired difference 2.5D − 2D per patient (40 patients, 4-fold CV, each patient averaged over 3 seeds); dot = mean, bar = 95% bootstrap interval. Dice: right of 0 is better.
Wrong slices past the ends: left of 0 is better.

Data: data/segthor_train_full/train, corrected labels (aorta separate); stitched validation volumes on the original CT grid. Regions from the ground truth per organ: ends = organ slices within 10 mm of its top or bottom slice, middle = the other organ slices, past = empty slices within 10 mm beyond either end. Dice over the voxels of those slices. 48 intervals are shown, so 2-3 are expected to exclude 0 by chance alone.
