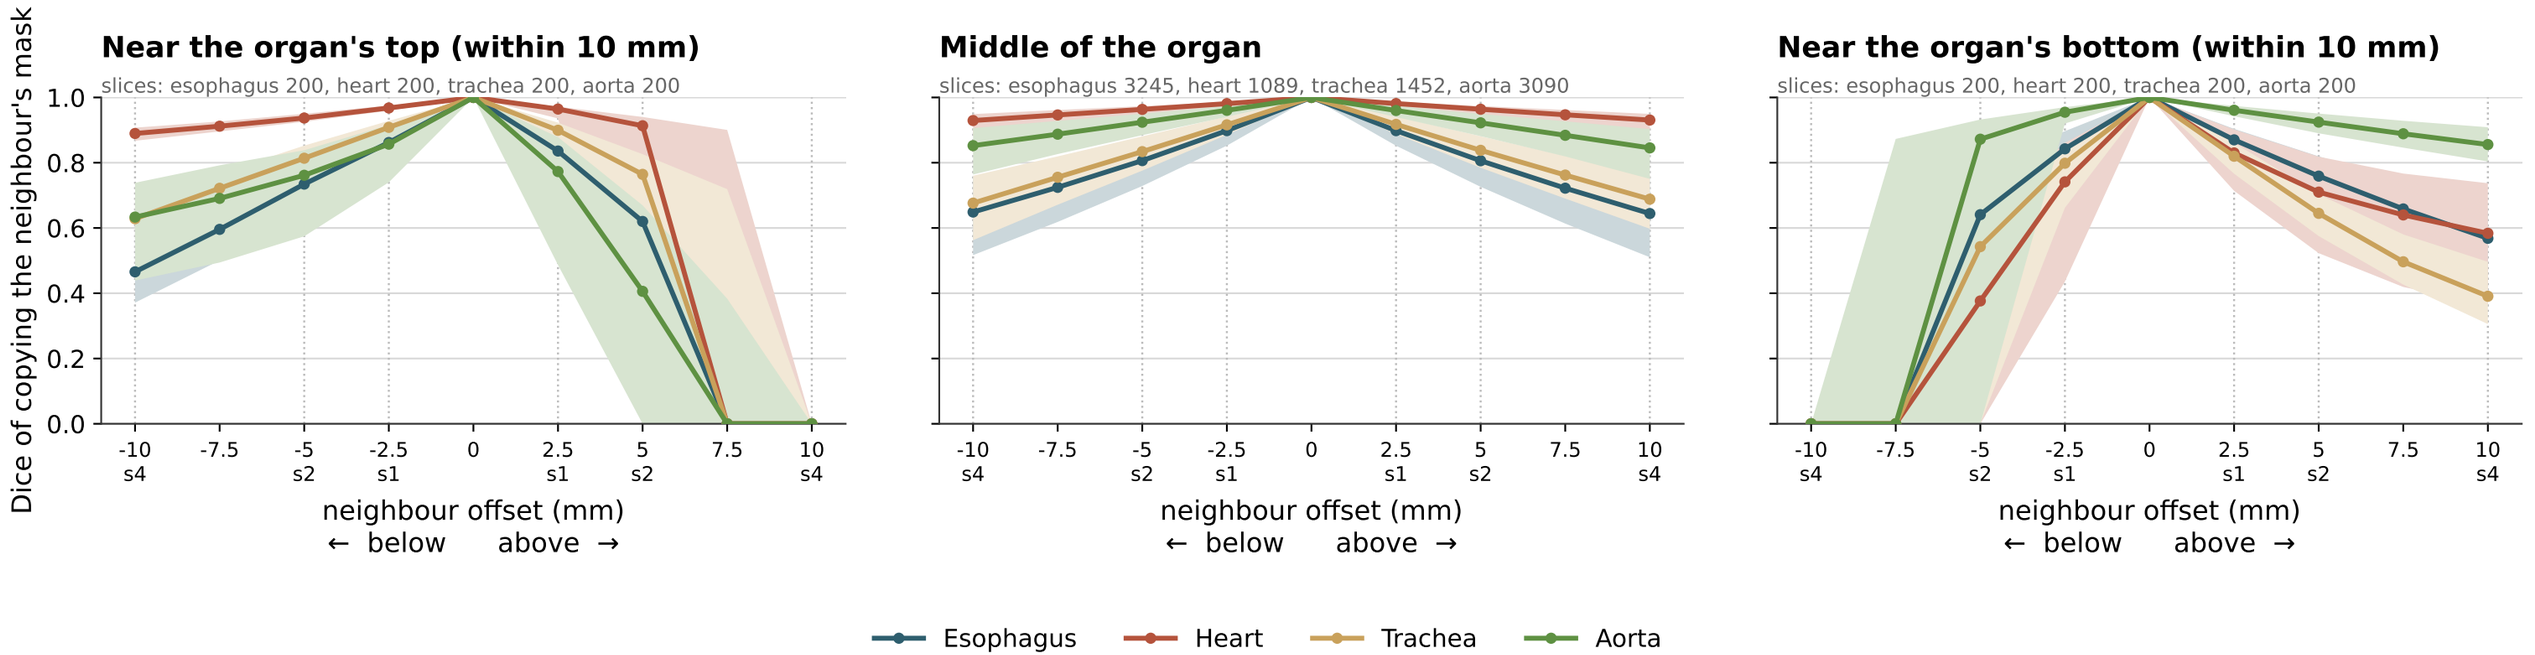
Inside an Organ the Neighbour Slices Are Near-Copies; Near Its Ends, and for Thin Organs, They Drift Fast

How well the organ mask on a slice nearby matches this slice (1 = identical, 0 = organ absent or moved). Median over all slices of 40 patients, band = 25–75%. Dotted lines (s1/s2/s4 under the axis): what a 3-slice 2.5D input sees at stride 1, 2 and 4.



Data: data/segthor_train_full/train, corrected labels (aorta separate), labels resampled along z to 2.5 mm (nearest neighbour, as the 2.5D runs); in-plane resolution kept. Top/bottom = centre slices within 4 slices of the organ's own most superior/inferior slice in that patient. Neighbours outside the scan are skipped.
